Emergent trees hold a high proportion of the regional diversity of epiphytes: 33% of all flowering epiphytes, and 50% of all filmy ferns described for Chilean temperate forests. Dry epiphyte biomass associated only with the emergent *E. cordifolia* trees in coastal forests was estimated in 10 t/ha. Epiphyte biomass may store up to 300 l of water in each emergent tree, and add 40-150% of photosynthetic biomass to the tree crowns.

Epiphyte diversity as well as distribution and composition of epiphytic biomass was investigated in two lowland and two montane rain forests in Ecuador. Species numbers of epiphytes per tree were slightly higher in the montane (22–41 in Los Cedros, 33–54 in Otonga)

in Yasuni, 19–32 in Tiputini),
however differences were not

An epiphyte is an organism that
grows on the surface of a plant
and derives its moisture and
nutrients from the air, rain, water
(in marine environments) or from
debris accumulating around it.
Epiphytes take part in nutrient
cycles and add to both the
diversity and biomass of the
ecosystem in which they occur,
like any other organism.
